»Common Garden Transplanting Mistakes«

Crops being consumed due to their high nutrients content, the application of agronomy determines highly the level of yield from the field at a given time.

Planting of crops at wrong time leads to a disaster of results such as poor ripening of crop fruits due to late planting and also too deep planting of seedling make plant rot while shallow planting floats over the plants due to lack of support.

Seedlings transplanting

When growing garden from transplants, seed in time space well and the root collar should not be buried under soil and similarly try to avoid transplanting during heat of the day and during super hot or sunny and windy days to minimize shock on the plants and eliminating any possibilities of drying.

Similarly, provide proper spacing to the plants and mulch the seedlings to moderate the temperatures extremes, mitigate moisture loss and keep soil's active top layer healthy. Because not watering immediately affects plants especially in dry soils, water thoroughly after mulching and soon after in a few days.

Finally pre soak plants before planting.
